### 1.2 OPERATING SYSTEM DEAL

As we have been saying for some time, we have been in negotiation with Acorn over the pricing policy for the replacement operating system ROM for the Beeb. Acorn's projected replacement cost started out at around £10, then rose to around £15, and perhaps as a planned concession in the politics of pricing, dropped again to £10 + VAT (=£11.50). This is the current price for a dealer upgrade; though if your current operating system is in EPROM, the dealer replacement will be performed free of charge.

As a result of our discussions, Acorn have agreed to let BEEBUG members have a replacement ROM at around half price. The ROM must be ordered direct from BEEBUG (at our new software distribution address in High Wycombe) and costs £5.10 + VAT (=£5.85). We are reasonably satisfied with this price, since it approaches what might be termed a "nominal" replacement charge (though £2.50 would have been nicer!). Moreover the 1.2 is really rather a good piece of firmware. We have had advance samples of the ROM for a number of weeks now, and the series one certainly has a useful number of features not expected from the original specs of the machine: for example extra graphics "fill" routines (see BEEBUG no 6) and the many extra \*FX calls - see the New User Guide for details.

The ROM will be supplied with simple fitting instructions. No soldering is required, but you will need to remove the keyboard (2 or 3 screws). Full details of how to order the new ROM are given on page 35 of this issue, together with an official statement from Acorn. Very large numbers of ROMs have been set aside for us over the next two months, and we are being supplied at the same time as the dealer network. Nevertheless, supply can never be guaranteed; and for this reason we are limiting the offer to one per membership in the first instance.

#### BEEBUG MAGAZINE

As you will see, this issue is in two parts: the main body of the magazine is accompanied by a twenty page supplement (unless ordered as a back-copy). This supplement contains advertising plus a series of items that will in general be updated monthly. We have received numerous requests for advertising space in the magazine, and it was this which prompted us to produce a trade supplement. There is now a vast array of products available for the BBC micro, and we hope that the supplement will provide a useful function in informing readers of an interesting cross-section of products.

On the other hand we have kept this separate from the main body of the magazine in this trial format, so that the latter may be set aside as an unencumbered reference book. To this end we are currently investigating a binder offer, and will be producing an index to volume one in the April 1983 issue.

We hope that you will find the supplement useful, and you may wish to use our new Members' Corner page, or Personal Ads Columns in the future. In any case this issue contains considerably more editorial material than even the last issue - since advertisements have been removed from the main body of the magazine, as have regular items such as discounts pages, user groups and so on.

In this issue, we give the results of our second competition - with prizes totalling over £800. At the same time - on page 48 of the supplement, a new competition is announced with prizes of a 14 inch colour TV/RGB Monitor, five Wordwise word processors and five copies of Acornsoft's Creative Graphics book. We are most grateful to Portatel Ltd., Computer Concepts, and Acornsoft for the donation of these prizes.

## IDEAS ON ANIMATION

by Colin Opie

This article describes how to produce remarkably smooth animation with BBC graphics, and is based on a clever technique used in a rotating cube program written by Roger Wilson and Laurence Hardwick of Acorn.

The first part of the article introduces the concept of logical plotting using GCOL and VDU19. The technique is then used to produce an animation sequence; and finally a listing of the rotating cube program is given. Note that if you are using a 16K machine, you should change Line 100 in fig.3 and Line 120 in fig 5 to MODE 5. Even if you have trouble in completely following the theory, the programs are well worth a look, and the procedures employed can be adapted for other uses.

### LOGICAL AND PHYSICAL COLOURS

A concept which is inherent in the use of GCOL and VDU19 is that of the difference between a physical colour on the screen (e.g. red, yellow) and a logical colour (ie. the number code which the computer uses internally and is willing to associate with a physical colour). If you look in the New User Guide (p223-on COLOUR) you will see that the maximum number of physical colours available in the graphics modes is sixteen, which includes 'flashing' combinations. Different internal logical colour codes are used for foreground and background colours enabling us to determine precisely what will happen when a character (graphics or text) is printed.

By way of example we will look at the options open to us when using screen mode 5. In this mode we are only allowed a maximum of four different colours on the screen at the same time. If we don't do anything to change the 'status quo' of this mode we will get the options given in fig 1. Note that the values 0-3 and 128-131 are the internal logical colour values used by the computer. Now lets take a look at GCOL and VDU19 to see how we can manipulate these facts to our advantage.

Foreground	Background	Physical Colour
0	128	black
1	129	red
2	130	yellow
3	131	white

fig. 1 logical colour values for mode 5.

### GCOL AND VDU19

The basis for this article lies in these two commands, so it is worth taking a good look at these. GCOL enables us to say how we want all future graphics to be plotted and which colour to use. It has two arguments and has the general form: GCOL P,C ; where P is the plotting method (in the range 0-4)

which is to be used, and C is the value of the logical colour to use for all future graphics work. Clearly in mode 5 any of the values given in fig. 1 (above) would be valid. The parameter 'P' can be as given in fig 2, and the position of the plotting operation will be determined by the PLOT and TAB commands. This latest table produces at least three new operations which we need to know about, those of OR, AND, and EOR plotting. We will take each of these in turn and concern ourselves, for the sake of simplicity, with just foreground colours.

P	Plotting Method
0	plot the colour
1	OR the colour with current screen value
2	AND the colour with current screen value
3	EOR the colour with current screen value
4	invert the colour currently on the screen

Fig. 2 methods of graphic plotting

P=0: In this mode we will simply plot the colour specified by GCOL. If the command GCOL0,1 is used then the future foreground colour will be in red. If we use GCOL0,2 then it will be yellow. It does not matter what colour was present on the screen at some position prior to another plot in the same position. The new colour will take over.

P=1: Here it is the logical OR of the new colour and the previous colour which will be used in the plotting operation. Type in the following program:

```
10 MODE 5: GCOL0,1
20 PLOT 5, 300,300
30 GCOL 1,2: DUMMY=INKEY(100)
40 PLOT 5,0,0
50 END
```

First of all you will see a red line -i.e. COLOUR 1- (because of the GCOL0,1 in line 10), and then one second later you will get a white line, though one might at first sight expect a yellow line (ie. colour 2). Initially each point on the line was at logical colour 1 (RED). We then set the logical colour to 2 (YELLOW), but with OR plotting; and "1 OR 2" has the logic value 3, (you can verify this by typing "PRINT 1 OR 2" in Basic). This is why we get a white line (logical colour 3) instead of a yellow one. (If this logical binary operation is new to you then see the articles on LOGIC in BEEBUG vol. 1 nos.5,6 (Sept & Oct)).

P=2: This will use the logical AND of the colours. If we change line 30 (above) to read: 30 GCOL2,2: DUMMY=INKEY (100) we can see the effect of this. Colour 1 (RED) AND Colour 2 (YELLOW) gives Colour 0 (BLACK) because "1 AND 2" has the logic value zero, (again see BEEBUG nos. 5 and 6 if this is unclear). Thus after one second is up the line disappears even though our specified foreground colour is yellow.

P=3: Using EOR plotting (and therefore a value of GCOL3,2) we will get the same result as with P=1 because "1 EOR 2" has the logical value 3. (To test this type "PRINT 1 EOR 2" in Basic).

P=4: This ignores the current colour setting and merely inverts the colour presently set. The inverse (or logical NOT) of colour 1 (RED) is colour 2, hence we get a yellow line.

Now let's take a look at the VDU19 command. This has the general form of:

```
VDU19,L,A;0;
```

where L is the logical colour we are referring to, and A is the code for the actual colour we wish to assign to it. Fig.1 shows the values set for screen mode 5 if we don't do anything to change it. Even though we are only allowed four different colours at any one time, we can, via the VDU19 command, say which of the full range of 16 physical colours we wish to use for each permitted logical colour.

For example: 12 VDU19,1,4;0; will set colour 1 to BLUE

14 VDU19,3,13;0; will set colour 3 to flashing MAGENTA/GREEN.

If you insert these two lines into your test program and reset GCOL in line 30 to GCOL0,2 you will see the effect of this. The interesting thing about the VDU19 call to alter physical screen colours is that it does so instantly. We can take advantage of this in a number of ways. In particular we can draw a new image in physical colour black, and then make it suddenly appear all at once, just by using an appropriate call to VDU19.

#### ANIMATION TECHNIQUES APPLIED

As an example of how these two commands can be used effectively we will take a look at a couple of programs for producing animation, and compare their effects. Type in the program in fig. 3 using the line numbers given. The animation is done by merely drawing the boat in a colour and then drawing it again in black to erase it, and so on. If you run this program you will notice that the picture flickers furiously and does not look very nice at all.

PROCSAIL is the procedure which effectively does all the work. If we change this procedure to use GCOL more effectively, we can get a smoother display. Change the PROCSAIL procedure and add in the PROCSHOW procedure as given in fig 4. To try and see what is happening consider the following.

The way this new technique works is to draw the new ship each time in physical

colour black, so that the jerky drawing process is invisible. We then suddenly make it appear by using the appropriate VDU19 call. You may have used the same idea when drawing a graphics screen for a game etc. - to prevent the user from seeing the drawing process. In broad terms the same technique applies here, but there is a complication - each of the new ships overlaps the previous one, so we actually use three different logical colours. Colour 1 is used for the first display and colour 2 for the second. On the third display we want to erase the display drawn in colour 1 but not the one in colour 2. This can be achieved by an EOR operation using the value we want to erase, ie. colour 1. Notice that this will give us (1 EOR 1) for the first display (ie. 0 = black) which is what we want. In the second display on the overlapped bits we get (3 EOR 1) which gives us colour 2, which is also what we want. Moreover the whole of the second display is now in colour 2. By 'showing' the relevant colour at each stage the shape can be made to move, hence our extra procedure PROCSHOW.

**\*\*Note\*** To use two colours for two 'displays' we actually require three logical colours, hence we lose the ability to have so many different colours on the screen at the same time. So in using the technique we gain in appearance but lose a little in multi-colour capability. Obviously this poses far fewer problems in MODE 2 which can display up to 16 physical colours all at the same time.

#### ROTATING CUBES

We are most grateful to Roger Wilson and Laurence Hardwick of Acorn for permission to publish the program which appears as fig 5. This uses exactly the same technique to generate a rotating cube. It is the main loop in lines 360-510 which is doing the actual work, and notice how it too needs to access a PROCSHOW procedure in order to highlight only the logical colours that are pertinent at any one time. We will be looking further at 3-D graphics and rotation next month. Meanwhile you can type in the program and sit back and watch. In case you want to experiment, here is a list of the main procedures and variables:

#### PROCEDURES (CUBE)

D, DRAW Draws the 3-D shape. This uses GCOL to set appropriate logical operations in order to create and erase each view.  
 MOVE Calculates the 2-D mapping coordinates for each new position, from the stored 3-D coordinates.  
 SHOW Enables given colours to be displayed, hence showing a particular view.

#### VARIABLES (CUBE)

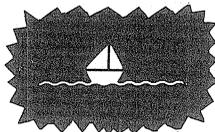

TX, TY, TZ Linear transformations in the three planes. If they are all zero then the cube remains in the same position, though rotating.  
 L, M, N, F Affect the displayed 'shape' of the cuboid. The values given display (would you believe) a cube.  
 NN, TIME These enable a display to be given in the top left hand corner of the time (1/100 sec) for each move. Notice that this is about a second.  
 COLOUR% Defines the colour of the rotating cuboid.  
 CX, CY, CZ These are the rotation factors in the three planes. If they were made to be all zero then the cuboid would not rotate.

## SOME NOTES ON PROGRAM SAVING

by Andrew Donald

---

The programs on the Welcome tape are all copyable, using the SAVE command, with the single exception of PHOTO. Investigation of why this should be has led to some useful insights.

What happens is this. When loaded the program shows a length of 09F4 bytes. If this program is now SAVEed the length will be shown to be 039C bytes, 0558 bytes are missing.

The missing bytes are additional code required for the image plotting in the program. The BASIC itself does end at 039C, and the SAVE command will only operate on the BASIC portion.

In order to save this program it is necessary to dump the BASIC and extra code as a unit and set the BASIC portion into operation when run. Looking at the memory map shows BASIC starts at 0E00 and we need to save 09F4 bytes from here. This may be done with the command \*SAVE "PHOTO" 0E00 +09F4 The default starting address for this code will be 0E00. That puts the total code onto the tape but how do we operate it?

The User Guide says to load a block of machine code and run it we should use the \*LOAD or \*RUN commands. However, since the bottom of this code is BASIC and since the tape format for both types of dump is acceptable to the BASIC loader, the command CHAIN"PHOTO" will load the entire block and then execute the bottom end BASIC. This is how the program operates on the Welcome tape.

The consequence of this facility is that BASIC and machine code, and/or data may be mixed in a more compact form than is possible with the usual mnemonic assembler allowed for in the interpreter. USR routines may be written above the BASIC: but take care to set LOMEM to prevent corruption of machine code when BASIC variables are assigned.

Also a machine code program may be kept in standard BASIC format by including a single BASIC line 1 CALL <address> and dumping with \*SAVE from 0E00 to the end of the code.

[We suspect that the extra code that needs to be saved is not actually a machine code PROGRAM but DATA. However the same still applies for saving. Ed.]

---

## QUICK QUIZ

### QUICK QUIZ

What numbers between zero and 999 have the special property that they are the sum of the cubes of their digits?

For example 234 is NOT a solution because 2 cubed + 3 cubed + 4 cubed does not equal 234.

The object of the quiz is to produce the fastest BASIC program to achieve this (checking all the way from zero to 999).

Please do not send in your results, we will publish our program and best times next month.

**HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS**

### SYSTEM CALLS

Did you know that all commands preceded by '\*' (eg. system calls such as \*FX, \*KEY, \*CAT etc.) can be in lower case? Andrew Crawhurst. Note also the abbreviation "\*" for "\*CAT".

---

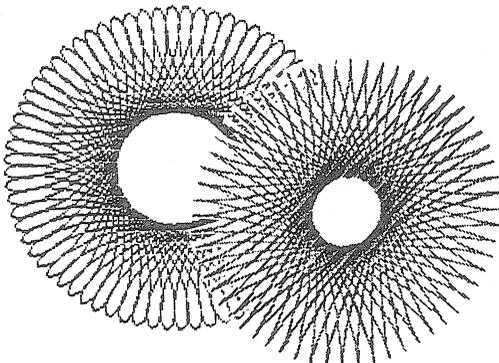

# MACHINE CODE SCREEN DUMPS FOR THE EPSON & SEIKOSHA

Here at last are the promised machine code screen dumps for the Seikosha and Epson printers. They are many times faster than the Basic dumps published earlier. Remember to take great care in entering the code, because machine code is much much harder to debug than Basic. Note that the Seikosha dump will not, as far as we know, work on a Seikosha 250.

## SEIKOSHA SCREEN DUMP (GP80A and GP100A) by Terry Bromilow

The program to be described is a machine code dump for the Seikosha GP80A and GP100A which will print in any graphics mode of the BBC machine. The program is most welcome as it enables you to print any horizontal strip of the screen, and takes only about 2.5 minutes to print a full screen. An additional feature is that if the screen to be drawn consists of several colours, it is possible to specify that only items of a certain colour should be printed. (Obviously the printer will print everything the same colour). When using mode 0, with its 640 dots horizontally, a compromise has had to be reached, as the Seikosha will print only 400. The solution adopted is to print every other dot.

### ABOUT THE PROGRAM

The program consists mainly of data statements, which are converted into machine code and cunningly stored in line 29480. That is why line 29480 consists, as it is typed in, of only X's. It is therefore essential that this line is typed in carefully as listed. Do not type in too few X's, there should be 168, although extras are okay.

Included in the program is a demonstration print of the exponential decay of a sine wave. It is by running this demo program that the machine code is generated, so do copy all of the listing, not just part of it. Once the code has been generated, the rest of the program can be deleted, leaving a very small and efficient machine code screen dump, which is activated as a procedure.

Storing the code in line 29480 makes it very easy to append to other programs, but results in restrictions on the 6502 instruction codes used. The codes 01 and 06 could not appear in it and there could be no internal absolute addresses, to enable it to work from any location. Also the appending process shown below must be used, since \*SPOOL will not work with this program. The advantages in implementing the machine code this way are that no dedicated RAM is used, and a fully relocatable

program results which may be further edited after the appending process. The procedure uses zero page locations 84 and 8F but these are saved and restored by lines 29120 and 29460 which may be omitted if not required.

### TO SET UP THE PROGRAM

The following needs only to be performed the first time that the program is used.

- 1) Type in the program as listed with great attention to the data statements, and save a listing of the full program to tape or disc.
- 2) Ensure that your printer is connected to the computer.
- 3) Now run the program. It should immediately prompt you for a mode. Select any mode (0,1,2,4 or 5) and enter the appropriate number followed by <return>.
- 4) The demonstration display should now commence. An exponential decay graph will be drawn on the screen, and then on the printer.
- 5) When the printer has finished, delete the following lines from the program;
  - Delete lines 29000 to 29090 inclusive
  - Delete lines 29130 to 29410 inclusive
- 6) Now save the resultant machine code, which is stored in the procedure called PROCGR. So use SAVE "GR" (not \*SAVE).

### HOW TO USE THE NEW PROGRAM

The screen dump is now in the form of a procedure, so to activate it we need to simply call it from the program that has produced the screen that is to be printed. This is done as follows;

- 1) Load in the program that will create the screen to be printed. This is accomplished in the normal way, using LOAD"programe".
- 2) Check that all the line numbers of this program are below 29000. If they are not just issue the RENUMBER keyword.
- 3) Now type in PRINT ~TOP-2 <return>. This will print a three or four character number on the screen. I will for the moment call this number XXXX.
- 4) Now reload the procedure created earlier using the following;
  - \*LOAD"GR" XXXX <return>
  - where XXXX is the above mentioned number.
- 5) Now type END <return>

### HOW TO CALL PROCGR

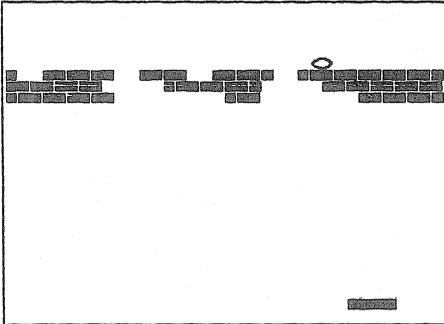

If you now list the program, you will find that PROCGR is located at the end of your original program, ready for use. It is ok to add new lines to the program or alter it in the normal way, without

fear of damaging the machine code. It is totally relocatable. All that remains is to call PROCGRP from your program at whatever stage you want the screen image to be dumped to the printer.

It is possible that you may wish to decide while your program is actually running, at what stage you want the screen printed. This is very simple and below is listed one way of achieving this. Insert at an early stage in your program; Say line 5 5 ON ERROR GOTO 28900 And then also 28900 PROCGRP(1023,0,15) :END Using these two lines, you could allow the screen to develop and then hit escape at an appropriate stage, whereupon the screen would immediately be printed. You can now save a copy of your program, including the PROCGRP within it. This may be done in the normal way.

SCORE 35 SERVES LEFT 1

Printout from BREAKOUT (issue 8)

PARAMETERS OF PROCGRP

The procedure must be called with 3 parameters. These are;

- 1. The upper Y coordinate of the strip to be printed,
2. The lower Y coordinate of the strip to be printed,
3. The colours to be printed.

The first two parameters are self explanatory, being the upper and lower limits of the strip to be printed. The coordinates must be given from the GRAPHICS origin, hence to print the whole screen the parameters would be 1023 and 0 respectively, and to print a narrow strip at the bottom of the screen would be 300 and 0. (see New User Guide for graphics details).

The third parameter determines which of the colours are to be printed. This number must be between 1 and 15. It will be ANDed with the logical colour of each point, and that point will only be printed if the result is non zero. To understand this very useful function, you must have an understanding of how AND is used as a bit operator. See New User Guide page 205 and previous BEEBUG articles. Also see NUG page 223 for details of logical colours. As an example consider a screen containing ALL of the following colours;

- RED Logical colour 1
GREEN Logical colour 2
YELLOW Logical colour 3
BLUE Logical colour 4

Using a parameter 3 of 1 would draw only Red and Yellow points.
Using a parameter 3 of 2 would draw only Green and

Yellow points.
Using a parameter 3 of 3 would draw only Red, Green and Yellow points.
Using a parameter 3 of 4 would draw only Blue points.

The most normal requirement of this third parameter will be to print all points on the screen, in this case use a value of 15. So to print all points on the whole screen use PROCGRP(1023,0,15).

EPSON MX80 III MACHINE CODE SCREEN DUMP by Timothy Powys-Lybbe

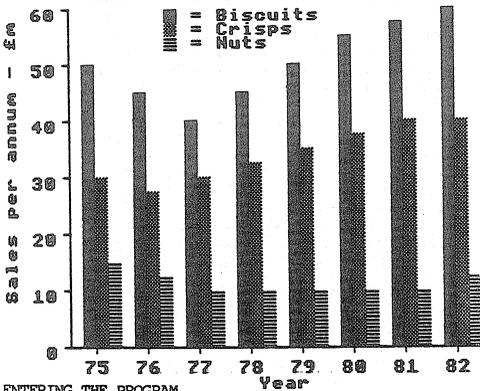

The following program was designed after reviewing a number of screen dumps kindly submitted by members. It combines the best features of these (I hope). It will print all graphics screens (i.e. modes 0,1,2,4 and 5) taking two minutes in MODE 0 and eighty seconds in other modes. The program automatically senses what mode is in use. The listing also includes a simple demonstration which

illustrates how to use the assembler program from within a Basic program. Alter line 20 for other modes.

There are two versions of the program - one for cassette (tested on O.S 0.1 and 1.0), and one for disc (tested on O.S 1.0). In both cases the machine code routine is stored in an area of memory below PAGE, and therefore requires no adjustments of PAGE or HIMEM. The cassette version is stored in the user area at &D00, and the disc version is stored at &A00. The user area at &D00 is corrupted by disc use, so we have used the cassette buffer and RS423 input buffer (at &A00) for storage. This means that the program cannot be used when RS423 input is in progress, but this is not likely to be a problem to most users.

Both versions can be saved and loaded transparently in a similar manner to the technique described by Gwyneth Pettit in BEEBUG No.7; and the cassette version is just short enough so that the 0.1 Operating System Bug Fix program can be included in the same area of memory, as long as the Bug Fix starts at the address hex &DD0. The program by Brian Carroll in BEEBUG No.7. works in the same way. Finally the dump should work with all operating systems and should also work across the Tube to a 6502 second processor.

### Snacks Ltd Sales History

#### ENTERING THE PROGRAM

Obviously entering an assembler program is difficult for those who are not familiar with assembler. The listing below uses the BBC Micro long variable name facility to make it easier to recognise any errors. Spaces are one problem; in the assembler program from lines 10040 to 10250 spaces are only needed after the names that start with a full stop, "LineGap" for example.

Note that for machines with a disc interface, alter line 10030 to:

```
10030 P% = &A00:[OPT PASS
```

Do not RUN the program unless you have first listed it to your printer and saved it on tape (or disc for the lucky few). This will save hours of re-entering if you have made fatal errors.

When you run the program, you should get a random picture drawn on the screen, and then this should be automatically copied onto the printer.

Once a successful printout has been obtained, you can destroy the Basic program and assembler code (though it would be prudent to keep a copy) and just use the assembler code stored at &D00 or &A00.

To save the machine code only, use the command

```
*SAVE"ScreenDump" D00 DD0 (cassette version)
or *SAVE"ScreenDump" A00 B00 (disc version)
```

To load the machine code back into memory at any time (transparently), use this command

```
*LOAD"ScreenDump" (cassette or disc version)
```

To print the screen from Basic after loading the machine code use the command CALL &D00 (or CALL &A00 for a disc system); see line 1050 for the listing. Remember though that on series one operating systems (ie 1.0, 1.2 etc) you must turn on the printer with a CTRL B (or VDU 2) before calling &D00 (or &A00), and turn off the printer at the end with a CTRL C (or VDU 3). Thus the command:

```
VDU 2: CALL &D00 (or &A00 for discs) : VDU 3
```

will be needed to print a screen. If you are using cassette and 0.1 operating system, you can save and load all of the function keys, the user characters, this screen dump program and Brian Carroll's bug fix. Execute:

```
*SAVE"Utilities" B00 E00 DD0 <ret>
```

You can then load this back in, and run the screen dump with:

```
*RUN"Utilities" <ret>
```

Thanks to Andrew Burke for the idea of putting all graphics modes on one short program, to J.H. Williams for his neat demonstration designs, to K.E. Hussey for his idea of fitting the program into page D hex for cassette use, and to all those others who have written to us on this topic.

## SPIROPLOT

by R.Sterry

This is a beautiful little program which generates pictures similar to those produced by a 'Spirograph'. You define the size of the 'disc' that you want to use and the position of a 'pen' within that disc (known as the 'locus' position). Many an hour can be spent playing with this program in trying to produce the magnus opus of computer generated spiroplots.

Some examples for you to try  
in order to get the idea of things are:

Disc Size	Locus
50	1.4
89	1.0
202	0.5
212	1.5
298	1.5

These examples should be enough to trigger your imagination. Happy designing!

```

## HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

\*FX254 CALL

M.E.Horton sent in this hint. It provides a simple way to turn your 32k computer into a 16k computer.

Try: \*FX 254,&40

Then press CONTROL and BREAK together. After this, you should get 'BBC Computer 16k'. It provides an easy way of making sure that your programs will run on both models. The call seems to work on a series 1 operating systems and is reset by \*FX254, &80.

[Ed: It seems that any value between 0 and 127 will have the same effect as using &40, and any value between 128 and 255 will do instead of &80. For example you could just use 0 and 255].

## USING FILES

by Sheridan Williams

Sheridan Williams begins a series of articles on the use of files on the BBC machine. It is hoped that this will be of interest to all those whose programs involve data handling, both on cassette and disc. The article begins at an introductory level.

All programs that perform data processing functions require some form of file storage, otherwise we cannot continue to process data from one day to the next. There are TWO main reasons why files are used:

1. To hold data over long periods.
2. To hold more data than can be held in the computer's main store.

There are three ways in which files can be held and these are:

1. In DATA statement..
2. On cassette
3. On disc

Choice number one (DATA statements) unfortunately does not rid us of the problem of limited memory space inside the computer. Choice number two (cassette) gets over that problem but introduces the problem of long and tedious reading and writing of the data to and from the file. Cassettes only read/write at about 100 characters per second, so to process a 25k file (not particularly large in realistic data processing terms) it would take 4 minutes. Also cassettes are severely limited because they have no capabilities for positioning the tape accurately anywhere in the file.

Thus if you wanted to change one field in just one record on a 25k file, it would take 8 minutes to do - 4 minutes to read the whole file and 4 minutes to rewrite it. You would also need a 32k machine for the file to fit.

Discs provide the best solution, however they are expensive compared to cassettes. There is no avoiding the fact that many data processing applications require the use of a disc, in this case the costs must be borne in mind. (See the December issue for a brief comparison of 5 disc drives).

### FILES, RECORDS, FIELDS

Before we look at the statements in BASIC and some routines for file processing, we must understand some of the jargon.

**File** - A collection of related records. An ordinary metal filing cabinet may contain several files, or just one file, or even none! Similarly a cassette or disc may hold several files. Examples of files would be: Payroll file, Library book file, Criminal file, Stock file, Customer accounts file.

**Record** - A set of information relating to an individual item in the file. A card index file contains individual cards, each card being a record. Examples are: Criminal record, Library book record, stock record.

**Field** - A subdivision of a record. For example, a library book record would probably contain some (or all) of the following fields: Book Title, Author, Publisher, ISBN.

For the purpose of demonstrating files we will work with the following file throughout this series of articles:

Filename: PEOPLE                      RECORD DESCRIPTION

FIELD	CONTENTS
1	Surname
2	Title
3	Sex (M or F)
4	Date of Birth

---

Suppose that we wish to write a program to find all the males in the file that is stored in DATA statements. The following program will do this:

```

10 PRINT"List of all males in the file"      50 UNTIL surname$="*"
20 REPEAT                                     60 DATA Bloggs,Mrs,F,240472
30 READ surname$,title$,sex$,dob$          70 DATA Jones, Mr, M,171066
40 IF sex$="M" then PRINT title$;"        80 DATA Smith, Mr, M,020155
";surname$                                  90 DATA *, *, *, *

```

It is rather tedious, and a severe limitation to hold a file in DATA statements. For example to add, delete, or amend a record held in DATA statements you need some knowledge of programming, or at least be familiar with the BBC machine because you are altering the program itself when you are changing the data statements.

So we turn to cassette and disc files. Commands associated with files are: OPENIN, OPENOUT, PRINT#, INPUT#, BPUT#, BGET#, CLOSE#, PTR#, EOF#.

For the rest of this article, all programs given will work on a disc system or a cassette system. [Beware if you have O.S. 0.1 because you will have to run the "Bug Fix" program (given in July 1982 BEEBUG) to cure the cassette filing bug]. The term for the type of file that we will be using in this article is a SERIAL or in some cases a SEQUENTIAL file.

A file must be opened before data can be written to it, and similarly it must be closed when you have finished.

On a disc system several files may be in use at once, for example a sophisticated Payroll package may require all these files to be open at once:-

```

Employee tax file
Tax table reference file
Employee name & address file
Tax authority payments file

```

For this reason, when a file is opened it is allocated a channel number.

For example, you open a file for output (ie to be written to) as follows:-

```
channel=OPENOUT"PEOPLE"
```

if you then PRINT channel you will find out what channel the computer has allocated when this file was opened (probably 17). You needn't ever know the channel number because you will always use a variable to represent it. Note that the same channel number isn't always associated with the same file, in another program you may find that the computer has allocated a different channel number.

If you try this in immediate mode you will hear the cassette relay click on, or the disc drive start. It is writing the 'header' containing the file name to the cassette or disc. If you now type CLOSE#channel then the cassette/disc would switch off, and you will have created a file, albeit an empty one. This is analogous to a filing cabinet with a label saying 'Employee file' on the drawer, but with nothing inside.

To write data to a file is quite simple - you use the PRINT# statement. (Make sure you have a cassette or disc in situ). Proceed as follows:-

```
10 ch=OPENOUT"FRUIT"      20 PRINT#ch,"Apple","Pear","Orange"      30 CLOSE#ch
```

If you want to prove that the data really has been put on the file then we must establish how to read the data back from the file. To do this you must open the file for input rather than output as we did before. We use the statement OPENIN. We are now going to input data from the file, but stop for a minute; how will we know when there is no more data on the file to read? The function EOF# is provided for just this purpose. EOF# returns either true (-1) or false (0) depending on whether the End-Of-File has been detected.

---

So we can use OPENIN and then a REPEAT UNTIL EOF# loop to control our input from

---

the file. This is done in the program below (lines 50-100). It reads back the data written to the file in lines 10-30 above. (You can join both of these programs to make one before you run them).

```

40 INPUT"Press 'return' when ready
to read back file",Q$
50 chan=OPENIN"FRUIT"
60 REPEAT
70 INPUT#chan,fruit$
80 PRINT fruit$
90 UNTIL EOF#chan
100 CLOSE#chan

```

[If you are using cassette, rewind the cassette before you read back the file].

Once the file is open you can write (print) as many items of data as you want to the file, obviously at some point the cassette/disc will fill up so this is the upper limit to the size of the file. Files cannot realistically be extended across to different discs or cassettes. It is wrong to open and close a file between each write operation.

Each time a file is open for writing, the data is written to the BEGINNING of the file, so that any data previously there is overwritten. For example this program will only read back 'Apple' even though you have written two fruits to the file. Lines 10-30 write "Tangerine" to the file, then lines 40-60 write "Apple" to the same file. However, lines 70-110 read (input) the data from the file, and yet you will see that there is only one fruit (Apple) on the file.

```

10 c=OPENOUT"FRUIT"
20 PRINT#c,"Tangerine"
30 CLOSE#c
35
40 c=OPENOUT"FRUIT"
50 PRINT#c,"Apple"
60 CLOSE#c
65
70 c=OPENIN"FRUIT"
80 REPEAT
90 INPUT#c,fruit$: PRINT fruit$
100 UNTIL EOF#c
110 CLOSE#c

```

If you think about it, you will probably say that this is ridiculous because you can never add anything to the end of the file, let alone modify one record in the middle of the file. Each time the file is opened for reading or writing the record pointer associated with that particular channel is set to the first record. There are theoretically three solutions:

1. Load the whole file into memory, make the modifications, then write them all back to the file. This is only feasible with a small file that will fit into memory.
2. Use two tape recorders, read one record at a time from the file on one recorder, if it doesn't need modifying then write it to the file on the second recorder, if it does need modifying then modify it before writing to the second recorder. Continue this process until the whole file is updated. However, the BBC micro doesn't readily support 2 cassette decks.
3. As in 2 above, but using two disc files, one for input and one for output. (Note that a disc can hold and process more than one file at once).
4. Use a "random access" disc file. (We will cover this topic in a later part in this series).

Next month we will look at the first of the three options above, taking examples from the cassette-based version of Masterfile.

## HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

### SIDEWAYS SCROLLING

The Beeb has a ready-made command to perform a sideways scroll: VDU23;13,A;0;0;0; where A represents the new position on the screen. See review of Creative Graphics in this issue for further details but try:

```

10 FORA=1TO200
20 TIME=0:REPEAT UNTIL TIME=100
30 VDU23;13,A;0;0;0;
40 NEXT

```

For the reverse direction, alter line 10 to: FOR A=200 TO 1 STEP -1

Order from Acornsoft Ltd., Vector Marketing,  
Denington Industrial Estate, Wellingborough,  
Northants NN8 2RL

There have been a number of rather mediocre books  
published about the BBC micro. This one stands head  
and shoulders above the crowd, and reinforces  
Acornsoft's reputation for excellence.

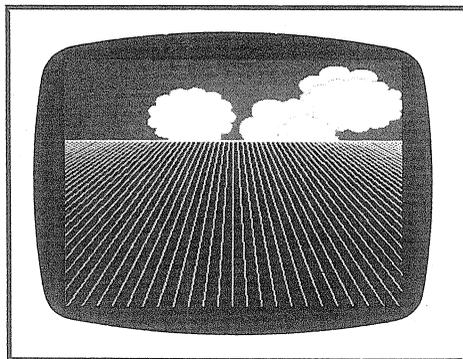

Its relatively small number of pages are packed  
with a wealth of ideas on the use of graphics on the  
BBC micro. The book is logically laid out with the  
following chapter headings:

1. Graphics Commands
2. Functions and Symmetry
3. The Third Dimension
4. Animation
5. Recursion
6. Pictures

It takes the reader who has a grounding in BASIC  
from an introduction to the graphics commands on the  
BBC machine, right through to the generation of a  
number of animated sequences which make use of the  
techniques developed during the course of the book.

The whole is skilfully managed, and the book  
contains fully documented listings of 36  
illustrative programs, many of which produce very  
nice visual displays of their own, and most of which  
will run with slight modifications on a model A.

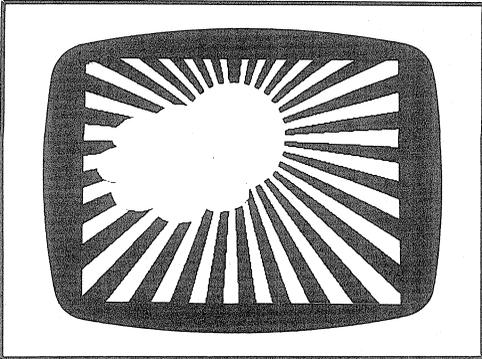

Moreover full use has been made of the advanced  
features of the BBC micro, including procedures,  
which play an important part in the structuring of  
the final animation sequences.

The one area of screen graphics that is excluded  
from the book is the user defined characters. The  
book concentrates on the kind of graphics that can  
be produced using the PLOT command. This  
intentionally omitted area might well provide the  
material for a sequel: but in the meantime  
Acornsoft are not giving away ALL the secrets of  
games such as Planetoid!

There is an accompanying cassette (£10.00  
extra) containing the 36 programs, but since most

are very efficiently written - and therefore short - it is not too much trouble to enter them by hand.

We publish below with permission from Acornsoft the listing of one of the final animated sequences, together with screen photos, to illustrate some of the techniques used, and the quality of the programs listed. This program - Windy Field - firstly generates a series of billowy clouds which float across a blue sky. A furrowed field is then rapidly generated. The clouds then sink below the horizon, and the horizon itself scrolls down. A new picture is then generated with a sun partly obscured by cloud. This picture then ripples through a series of colour sequences (which may be speeded up by pressing any key). As you will gather from the length of the program, this is all achieved very efficiently.

One of the most interesting points to note is the use of the command VDU 23;13,X;0;0;0; to scroll the screen sideways. X is simply the degree of scroll leftwards. To scroll right, set this high, then reduce it by stages. This beautifully simple undocumented command is typical of the kind of things that may be learned from this book.

Title: 30 Hour Basic 254 pages  
 By: Clive Prigmore price £5.95  
 Reviewer: David Graham

This book bears the BBC owl logo, and is promoted in connection with the Computer Literacy Project. With the word "BBC" on both the spine and the front page, would-be purchasers are likely to conclude that this is a course for users of the BBC micro. In this they would in my view be mistaken. The programs in this book were written for, and tested

on a PET - since BBC micros were not available when the course was designed; and this text book ignores all the innovative features of BBC Basic. For these reasons BBC micro users would I believe generally do well to steer clear of it.

Before backing up these allegations let me present the plus side of this book. It is quite well produced, gives you a lot of pages for your money, it has a spiral spine so that it will lie flat while you are keying in programs; and above

all it is a structured text (though unfortunately one that does not teach structured programming), and it has self assessment questions at the end of each unit.

But let us see just what a BBC Micro user would miss if he followed the course.

There is nothing on procedures.  
 There are no REPEAT..UNTIL loops.  
 There are no IF..THEN..ELSE statements.  
 There is almost no use of long variable names.  
 There is nothing on integer variables.  
 There is nothing on sound or graphics.  
 All modes but Mode 7 appear to be ignored.  
 The TAB function has no Y dimension.  
 There is nothing on error trapping.  
 The RND function is not properly used.  
 There is nothing on \*FX calls, the function keys, or the use of TIME, PAGE, HIMEM etc.

This is a quite unbelievable list of omissions, but the BBC micro user has more to contend with. The listed programs are of a general nature, and contain many additional notes with advice for the BBC micro owner. For example in the dice throwing program listed on p. 170 it says "BBC: 60 omit line". Line 60 is the RANDOMIZE command available on a number of extended Microsoft BASICs, but not on BBC Basic. Its function is to shuffle the random number generator called by the command RND. Deleting the line will remove the randomness of the results. BBC

Title: The BBC Micro Revealed 144 pages  
 By: Jeremy Ruston price £7.95  
 Reviewer: David Graham

This book bears the same form of title wording as the first rate book on the PET - "The PET Revealed" by Nick Hampshire - and the companion volume - "The Vic Revealed" by the same author. But Jeremy Ruston has not in my view produced the same calibre of magnum opus.

In the first case the Ruston book carries no index OR contents page, so that it is difficult to find your way to its various sections without reading from start to finish, and even then subsequent reference will not be easy.

In fact the book contains four sections  
 Section One (p5): The 6845 CRT  
 Section Two (p36): Memory Locations  
 Section Three (p102): Basic Program Storage  
 Section Four (p109): Basic Variables Storage

Section one looks, as its title suggests, at the video controller chip, and its registers, and shows a number of tricks that can be achieved by addressing them directly.

Section two is by far the longest section of the book, and is the most problematic. Essentially it gives the functions of a whole series of locations in RAM that are used by the operating system to store such things as cursor coordinates, or current

Title: Assembly Language Programming for the BBC Microcomputer 305 pages  
 By: Ian Birnbaum price £8.95  
 Reviewer: Colin Opie

Published by Macmillan Press, this book helps enormously to fill a gap in readily available publications concerning different aspects of home computers. It is also a pleasure to see such a book printed and published in England, rather than yet another import from across the water, though one

owners should have been told to replace line 60 with 60 A% = RND(-TIME), which has the same effect as RANDOMIZE.

There are two points to be made here. Firstly the BBC owner should not have to follow a number of corrections in order to make a program run on his machine, and secondly the corrections are not always correct, and in some cases are left out altogether. For example the program on p. 174 will not run because the RANDOMIZE has been left in.

If you are a relative beginner to BASIC, and are using a more primitive computer than the BBC micro, then this book could certainly be of use, though its lack of machine-specific treatment and absence of graphics will limit this use. But if you are using a BBC micro then you should not buy this book. I say this partly because of what the book lacks; and the list above makes very depressing reading; but perhaps even more so for a second reason: the relatively unstructured programming that this book fosters.

If you were learning to fly a jumbo jet, you would get only relatively little use from a Gipsy Moth manual - and you might even learn some bad habits. This is presumably why the NEC and BBC are getting together to bring out a real jumbo jet version in the near future - we will keep you informed.

palette, and also buffer areas. Generally speaking the BBC machine's FX and OSBYTE calls make such details somewhat redundant for normal programming purposes, added to which, if you do PEEK the locations given by Ruston in a program of your own, then it will not work across the Tube. Having said that, there is a more serious problem. Ruston has done his detective work on a machine fitted with a 0.1 operating system; and when I tested a sample of the locations specified, none of them worked with the series one (1.0) operating system that I was using.

The largest section of the book is therefore unfortunately rendered out of date with the advent of the new operating system; and although a note at the start of the section makes this clear, there is no warning on the cover to alert the reader to this fact before he purchases the book.

Section three usefully explains the way in which BASIC programs are stored in memory and contains a neat program for listing all of BASICs reserved words with their tokens, direct from the machines' look-up table. Section four discusses the storage of variables, and like sections one and three makes interesting reading; but even without the O.S. 0.1 problem the book can never be "destined to become the bible of the BBC user" as Personal Computing Today is reported to have claimed: the ground that the book covers is far too limited. The BBC micro is a very complex machine, and the Bible is a very LARGE book.

would expect this as the book is concerned with the BBC computer.

In essence I believe the author has done a first rate job. Many books exist on 6502 Assembly Language programming but there is a definite need to apply low-level techniques to a particular machine. The operating system and general environment of different machines means that varying facilities are available to individual users. The author has exploited and discussed well the art of 6502

# DISC ROUNDUP

## MEMORY SHIFT ROUTINE

Object: To run large cassette programs from disc.  
Method: Load software from disc and then shift it down.

Many existing cassette programs are too large to run on a disc machine. The reason for this is that a cassette machine is able to start storing BASIC programs from location &E00. In a disc system this start location is &1900, the area between these two locations being used for various disc operations - a loss of about 2.5K of program memory.

When the need arises it would be useful to retrieve this space so that a large cassette program can then run on a disc system. To do this automatically we need to load the program from the discs into the normal program area at &1900, shift it down to &E00, set up a few variables and then run it.

Given below is a one line program which will define one of the function keys to perform this

'shift+run'. Type the program in and save it on disc with the name "SHIFT". Each time you need to set up the function key type:

```
CHAIN "SHIFT" <return>.
```

Assuming the function key is set, to shift a program simply LOAD it into memory and press function key 9. This will automatically run the program. If you ESCAPE from the program you need only type RUN to restart it. Pressing BREAK will re-instate the disc system but the program will now be lost from memory.

Program:

```
10*KEY9FORI%=0TOTOP-PAGE STEP4:I%&E00=I%&1900:
NEXT|MPAGE=&E00|MEMD|MLMEM=TOP|MRUN|M
```

Note that the SPACE between the words PAGE and STEP is important.

In 'Practical Computing' (FEB'83 p.71 - listing 2) there is a machine code program which you can append to the beginning of your programs to perform this shift operation - though we have not tested it).

CNO/RP

## AUTO START

Object: To run a program automatically when shift and Break are pressed simultaneously.  
Method: Use \*OPT 4,3, \*BUILD and !BOOT.

When using a BBC micro with discs, an option is available to automatically perform a \*RUN or CHAIN or \*EXEC function just by pressing the shift and break keys simultaneously. The following shows the steps necessary to define the user keys automatically in this way.

The file of key definitions is created with the \*BUILD utility. The special file MUST be named !BOOT (the reasons for which are of no consequence).

Execute the following:

```
*BUILD !BOOT <return>
1 *KEY0 |ORUN|M <return>
2 *KEY1 |N|LLIST|M|O <return>
.
.
.
9 *KEY8 |O|B|LLIST|M|O|C <return>
10 *KEY9 DIMP%-1|MP.HIMEM-P%, TOP-PAGE|M <return>
11 <press ESCAPE>
```

Follow this with: \*OPT 4,3 <return>

Line numbers are given automatically by the \*BUILD command and are always in steps of one. At the end of each line press the RETURN key, and at the end press the ESCAPE key (just as the AUTO command is used in BASIC).

The command at the end of the above sequence, \*OPT 4,3 sets a marker on the current disc to indicate that the file should be brought into memory with the \*EXEC command. This takes place when you hold down the shift key, press and release break, wait a second or two and release the shift key. If you release the shift key too soon then an ordinary BREAK will occur. Different values of n for \*OPT 4,n will indicate:

```
(n=0):NO ACTION;
(n=1):CHAIN THE FILE;
(n=2):*RUN THE FILE.
```

In all cases the file must be named !BOOT.

In some respects you can achieve greater flexibility by using !BOOT to chain in another program. This simply involves making line one of !BOOT take the following form: CHAIN "D.name", where name is the name of the program that you want to auto-boot, and D is the directory that it is in. The program could be a keyset routine, as above, or it could be a disc menu, or just a favourite program.

RP

## TEXT FROM DISC

Object: To read in text directly from disc during the running of a program. This is extremely useful for providing program instructions etc, without taking up valuable memory.

Method: Use \*TYPE (fsp) and \*BUILD (fsp).

THE COMMAND \*TYPE (fsp) in a program will cause a text file with numbered lines to be sent directly to the screen from disc. If the file contains more than a screenful of text, VDU14 (Control N) may be used for paging purposes. The text file can be easily generated using the \*BUILD command.

For example, suppose you wish to provide the

instructions for a game in this way. You could begin by typing \*BUILD \$.TEXT1

then type in the text (the line numbers appear automatically), and the text is automatically saved to disc under the title \$.TEXT1. To escape from \*BUILD, press ESCAPE.

In the games program, the following can be used:

```
80 PRINT "INSTRUCTIONS?"
90 ON INSTR("YyNn")GET$ GOTO
100,100,130,130 ELSE 90
100 VDU14
110 *TYPE $.TEXT1
120 VDU15
130 REM ** MAIN PROGRAM **
```

DEG

**MERGE**

Object: To merge 2 programs.  
Method: Use \*SPOOL and \*EXEC.

To add program A to program B, where A could be a procedure or second program.

1. Load program A into the machine.
2. Renumber program A so that the two sets of program lines do not clash. It is usual to make the line numbers of A greater than those of B.
3. \*SPOOL "name" <return> where name is any name to be applied to program A.
4. LIST <return>

**5. \*SPOOL <return>**

This process creates an ASCII file of program A on disc - i.e. it is not stored using tokens for Basic commands. To append this to program B, continue as follows:

6. Load program B
  7. \*EXEC "name" <return>
- This completes the operation. The \*EXEC command reads in data from disc as if it came from the keyboard (hence the need to de-tokenise the Basic with \*SPOOL).  
Note that where line numbers clash, those of A will obliterate those of B.

DEG

**ACCIDENTAL PROGRAM LOSS**

Object: To avoid accidental program loss.  
Method: By keeping backup copies, and 'locking' files on disc.

To cover yourself against accidental program loss always keep a backup copy. These can be conveniently saved in directory B. Thus use:

SAVE "TEST1"

and also

SAVE "B.TEST1"

To be doubly sure, you can use \*ACCESS (fsp) L to "lock" a file, and prevent it from accidental erasure. Also it is best to keep the backups on a different disc in case of disc failure.

**BWARE OF \*COMPACT**

When you use \*COMPACT to compact a disc it will wipe out programs in memory. This creates an easy trap for the unwary. Suppose you have just finished developing a program, and decide to save it to disc. You try, but are informed that the disc is full. You are sure there is plenty of room on the disc so you \*COMPACT. You may have been right, but you will not need the space now, since \*COMPACT will have destroyed the program that you were about to save.

DEG

**MICROWARE DISCS**

We reported in the Disc System Review in our last issue that we had a drive fault on one of Microware's 100k drive units. We have since tested two similar units of theirs for a period of several weeks, without the recurrence of the fault. This suggests that the reported fault was not typical of the batch. At BEEBUG we have purchased one of Microware's larger drives, and have had no problems with this one either.

DEG

**NO DOS MANUAL & NO UTILITIES DISC**

If you order a disc interface from Acorn, you will not receive an operating manual for the system. Acorn's policy has been to supply these, and a utilities disc (essential for formatting discs before use) only when you buy an Acorn drive. As we said in our last issue, it was not acceptable in our view to sell a product (i.e. a disc interface and operating system) and then refuse to provide a manual for its use. We have been in discussion with Acorn about this, and they have decided to sell the utilities disc and manual together at a price of around £30, obtainable from Vector Marketing. This is clearly pretty expensive, but it does provide one way out for those stranded with non-Acorn drives and no way to use them.

In the next issue, if all goes well, we shall be publishing a disc formatting program together with details of the DFS (Disc Filing System) commands. (We have already given brief notes on these DFS commands in BEEBUG no.8 p.9).

DEG

**HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS****\*FX18 CALL**

Those of you lucky enough to be running an OS from 1.0 onwards may like to be reminded (or informed!) of the \*FX18 instruction. This will reset the user defined keys so that they no longer contain character strings. Thanks to David Hoffman for this one.

**DEFINING KEYS**

Roger Wilson has noted that under certain circumstances a colon can not be used in place of IM when defining strings for keys through the use of \*KEY. The important point is that colons can only replace the newline code when the resulting string might be interpreted as a sensible BASIC line. For example, OLD can be followed by the newline character and other text, but it may not be followed by a colon because it cannot be part of a BASIC program.

**LAST LINE**

Douglas Nunn has found a way of quickly determining the last line number in your program. Press the (CTRL) and (SHIFT) keys down and then hit the (ESCAPE) key twice. On releasing the keys the message "Escape at line XXXX" will appear, where XXXX is the last line number used. This is especially handy after renumbering, or when appending programs to each other. The operation works on any OS.

---

## BBC BASICS – PROCEDURES –

by Rob Pickering

---

This month our column for the less experienced user covers procedures and their use in structured programs.

### WHAT IS A PROCEDURE ?

Although it is perfectly feasible to write programs for the BBC Micro without any knowledge of procedures, there is no doubt that their correct usage leads to a far superior program. But beware; using procedures wrongly can be much worse than not using them at all!

Think of a short part of a whole program, which carries out one minor task within the program. A few lines which, say, wait for the user to press a key before continuing. Assume that this minor task will be performed several times within the program, which is fairly typical. We could enter the same lines at each stage of the program where it is required, but this is tedious and takes up a lot of memory. What we do is make the relevant group of lines into a collective unit called a procedure. So you can think of a procedure as being a section of program which performs a given task as many times as required. It is similar in some ways to a subroutine (ie. using GOSUB...RETURN) but has certain advantages over the subroutine.

Each procedure is given a name to distinguish it from other procedures. A procedure name is very similar to a variable name, but with two real differences:

- (a) they must always start with the keyword "PROC" in order to distinguish them from variable names,
- (b) they may not end with a "\$" or "%" symbol.

Choosing an appropriate name for a procedure is very important, not only to make the program understandable to other people, but also to help yourself to remember what all the procedures do. Since the purpose of our example procedure is to wait for the user to press a key, it seems sensible to call it "PROCwait". Note also that using lower case letters for the name helps to make it clearer to read. Here then is our example procedure in full:

```

100 DEF PROCwait      120 key=GET
110 *FX15,1          130 ENDPROC

```

As you can see this is only a simple short example and as such it is not typical of the usual length of procedures. You will notice that line 100 starts with the letters "DEF", short for DEFINITION. It simply informs the computer that this is the start of a procedure that we are 'defining'. We only have to define a procedure once within a program, then to use it we simply state its unique name. For instance, here is an example of how we might use PROCwait within a program. Try it out and see what happens. Line 40 is particularly important here since it stops the computer trying to execute the procedure an extra time.

```

10 PRINT"Press any key to continue..."
20 PROCwait
30 PRINT"Thankyou."
40 END

```

Notice that we do not need to know at what program line the procedure starts in order to use it. The BBC Basic holds a list of where the procedures are in the program, each location being stored when the procedure is defined. This means that when you use a procedure the Basic does not have to search all the way through the program in order to find the right one, hence obtaining fast operation. You should also realise that there is nothing declaring which instruction to go to at the end of a procedure. BASIC takes care of this for us as soon as it reaches the ENDPROC statement, passing execution back to the instruction following the one which called the procedure.

---

---

**PARAMETERS**

You will inevitably have heard of parameters, but may not know what they are, or what their purpose is. To explain how they are used in the context of procedures, we will consider a variation upon our previous example of a procedure, in which we would like to wait for a number of seconds before continuing, rather than waiting for the user to press a key. We will initially assume that the delay time is fixed at five seconds. This time the procedure is to cause a delay rather than waiting, so a sensible name would be "PROCdelay", as given below:

```

100 DEF PROCdelay          130 REM Do nothing
110 TIME=0                140 UNTIL TIME>100*5
120 REPEAT                150 ENDPROC

```

Now to cause a five second delay we need only to use the statement "PROCdelay". But uses for a fixed delay are comparatively few. It would be far more useful to have a procedure that would wait for a specified length of time, but be able to specify that time when we use the procedure. One way to do this is to replace the number 5 with a variable in line 140 of the definition, then we just store the required number of seconds in that variable before using the procedure. However, this is a very bad way to use a procedure (which will be explained in due course). What we should do is use a PARAMETER. Look at the procedure below:

```

100 DEF PROCdelay(secs) 130 REM Do nothing
110 TIME=0              140 UNTIL TIME>100*secs
120 REPEAT              150 ENDPROC

```

A parameter is simply a value which will be used by the procedure in order to carry out its task. We use the expression "parameter passing" for the way in which values are passed from the main program into the procedure. Here, the procedure definition includes a Parameter, ( a variable named "secs") which will determine the number of seconds delay. The variable name "secs" in the definition applies to a variable which will exist in the locality of the procedure only. This concept of 'LOCAL' and 'GLOBAL' variables requires careful consideration.

**LOCAL AND GLOBAL VARIABLES**

Something which exists inside a procedure definition is said to be "LOCAL" to the procedure. A reference to something outside the procedure is said to be a "GLOBAL" reference. When a variable name is given as a parameter in the procedure definition it does not then use a variable of the same name from the main program. What happens is that when we use the procedure we must give a parameter there too. The value given in the call to the procedure is automatically copied into the procedure's own local variable. An example will help to make this clear.

```

10 secs=100                70 END
20 FOR s=1 TO 4           100 DEF PROCdelay(secs)
30 PRINT"Value of        110 TIME=0
secs in main=";secs      115 PRINT"Value of secs in PROC=";secs
40 PRINT"waiting ";s;" 120 REPEAT
seconds."                130 REM Do nothing
50 PROCdelay(s)          140 UNTIL TIME>100*secs
60 NEXT s                150 ENDPROC

```

Enter and Run the complete program above which demonstrates that the variable called "secs" in the procedure is actually a different one from the variable "secs" in the main program. In the main program "secs" is simply set to the value 100 and not used, but the fact that the variable of the same name within the procedure varies demonstrates that they are separate. Also notice that the value of "s" in the main program is copied (passed) into the procedure parameter "secs" automatically as the procedure is called with "PROCdelay(s)".

It is not necessary to give a variable name in the procedure call, e.g. the command "PROCdelay(5)" would be perfectly acceptable, causing a five second delay. The early user guides stated that it was not possible to pass strings to procedures. This is not true, you may pass strings to procedures, but remember that the type of parameter MUST match the type of variable in the definition. A fact which limits the

---

usefulness of procedures in BBC Basic is the anomaly that parameter passing techniques cannot be applied so as to pass a value back to the main program through the use of local variables, (see article in BEEBUG vol.1 no.3, p26).

Local variables are not limited to those which we use as parameters, in fact we can make all the variables within a procedure local to itself. To achieve this we are provided with the BASIC command "LOCAL" which is followed by a list of all the local variables. The effect of doing this may not seem very important, but it is. Using all procedure variables as local means that you are not relying upon a specific variable existing within a program, and consequently the procedures become of common value to more than one program. It means that you can take a procedure from someone else and need only know what task it performs, its name, and what parameters it needs. You don't have to worry about it upsetting any variables in your own main program. The whole idea of having a collection or library of common procedures is very important, preventing unnecessary duplication of effort and allowing programs to be written much more quickly. Looking back through past issues of BEEBUG you should come across some useful procedures in our "Procedure/Function library" column - BEEBUG vol.1 no.5 p.28 carries an index.

#### STRUCTURED PROGRAMS

An important topic related to the use of procedures is that of structured programming. To explain what this is to newcomers who may not have encountered it before, we could say that it is a way of writing programs so we can actually see what they do. The first section of the program is called the MAIN section and contains generally very 'readable' code, calling upon each procedure to carry out its task when it is needed. The other main section of the program is merely a collection of all the procedure definitions. This 'standard' layout is exemplified by the following typical program. See if you can tell what it does without having any idea of the actual programming involved in the definition.

```

PROctidy_up
END
REM *** DEFINE ALL PROCEDURES
DEF PROCxxxxxxxx
...
...
ENDPROC
PROCoption_menu
choice=FNooption
DEF PROCxxxxxxxx
...
...
ENDPROC
IF choice="C" PROCcreate_file
...
...
IF choice="E" PROCedit_file
...
...
IF choice="U" PROCupdate_file
...
...
UNTIL choice="STOP"
DEF PROCxxxxxxxx
...
...

```

Without much difficulty we can see what this program might do. This is shamefully un-typical of most programs we see in magazines, even BEEBUG. It is a reflection of the way in which few people ever sit down to write a program knowing what they want it to do. Just as they get started they suddenly think of something else it could do and squeeze it in where it shouldn't be. Then there are the other problems that they find something doesn't work and decide to remove it. Of course, they can't find all the little bits concerned, and confusing pieces are left where they shouldn't be. The GOTO statement is another 'nasty' leading to over complex programs. The ideal is to avoid GOTO statements as far as possible because they tend to foster bad program structure.

So if you are just starting out in programming, beware of the messy badly designed programs that your forerunners have written. None the least of which is me!!

## SOFTWARE UPDATE

In this column we will be bringing you updates and ideas for use with programs in the software library - this will include the word processor package Wordwise.

### DISC CONFIGURATIONS

At present all BEEBUGSOFT programs are cassette-based. To load them on a disc machine execute TAB/BREAK (or \*TAPE) before loading. Note however that some programs (eg. 'MAGIC EEL') will run out of memory unless you also type PAGE =&E00 <return> before loading. This is necessary because machines with a disc interface fitted use an extra 3K of memory for the disc work-space, unless you reset PAGE in this way.

### MASTERFILE

Instructions are given in the documentation of Masterfile to configure it for printer output. As the documentation says, the lines to look for (2000-2999) are in the FIRST program (ie. the header) - A number of members could not find them because they were looking in the main program.

### MOON LANDER

Keyboard responses on MOONLANDER can be improved by employing the negative INKEY function. To do this make the following alterations:

```
450 IFINKEY(-82)GOTO610          470 IFINKEY(-103) YS=YS-0.04:FUEL=FUEL-1
460 IFINKEY(-104) YS=YS+0.04:FUEL=FUEL-1    480 IFINKEY(-68) K=K-0.01:FUEL=FUEL-2
```

### WORDWISE IDEAS 1 - (More next month)

When editing text, try using option 5 - Search and Replace (Selective). This will accept very long strings, and spaces are permitted, allowing whole phrases to be corrected. This is much quicker than working through the text with the cursor, and performing manual corrections. You can also press Return on an empty replace string, and then press Escape when Wordwise asks whether to replace it or not. This will leave the cursor at the point required, ready for manual editing. Note that for all operations under option 5, the search is only carried out from the current cursor position. This enables you to work your way through a text very efficiently.

## INFO INFO

### ON ERROR BUG

Thanks to Eddie Atherton for highlighting this one. There appears to be a small bug associated with the ON ERROR GOTO statement. Try typing in the following mini program exactly as listed, including the REM and comments. Then run it, hit escape to exit and relist it. The result is a corrupted program.

This only happens when the REM and comments immediately follow the GOTO, and actually include a keyword. The computer has attempted to tokenise the keyword ON ERROR, even though it is only a comment.

```
10 ON ERROR GOTO 40: REM ON ERROR EXIT      30 PRINT"this routine"
20 PPRINT"Testing"                          40 END
```

### MORE JOYSTICKS

We received a review model of another joystick from CompUtopia Ltd of Leighton Buzzard. They are 'T' shaped joysticks with a 2 dimensional paddle at the top and a small push-button on the stem. Their size and shape make them easy to hold and there is no doubt as to which way round you should use them. The push-button is in a convenient position for 'thumb' operation, though its small size could give rise to a slight 'imprint' on your thumb if you play for an hour or so. Value for money: they are as good as others in the same price bracket, and certainly as sturdy.

Sold as a pair for £14.50 (inc. VAT) plus p & p, they are available from CompUtopia Ltd., 30 Lake St., Leighton Buzzard, Beds. LU7 8RX. Tel: (0525) 376600.

Program tested on  
0.1 and 1.1 O.S.

## PROGRAM COMPACTER (Revisited) (16k)

Text by Colin Opie    Program by David Tall

In the DECEMBER (BEEBUG vol.1,no.8) issue we had an article on compacting Basic programs. The concept of being able to squeeze large programs into a small space seems to have stirred the imagination of a number of members. Perhaps a craze has been started which will be second only to space invader programs?

David Tall wrote to us a number of times with suggestions on how to improve the initial program. The problem with the published one was that because of the way in which destination line numbers are stored for GOTO, GOSUB, and RESTORE, the program will occasionally corrupt the program to be compacted, because it mistakes a destination line number code for a REM token; though this never happened in our tests. The problem with modifying the compacter was that it would become too long for the area of memory allocated to it.

The 'super-compacter' presented here, written by David Tall, gets around all these problems. As it is in machine code it is fast, will fit below the cassette PAGE boundary, and work regardless of whether or not a disc system is fitted. It will also remove comments from assembler listings. All in all we think that you will like this update on what is an extremely useful utility.

### OPERATION

The program copes with three independent choices. When used it offers the choices as follows:

```
SPACES?    To remove spaces
REMS?      To remove Basic REMs
COMs?      To remove Assembler comments.
```

If you don't have any assembler code then it will not matter what reply you give to the third choice. Note also that whereas REM deletions will remove the whole REM, deleting assembler comments only affects a comment from the \ symbol up to, but not including, the next separator (ie. a colon). Therefore:

```
120 A=B:REM this is a remark:X=Y
reduces to:                    120A=B
```

```
but:                    200 [LDA#70\this is a comment:STA#72]
reduces to:                    200[LDA#70:STA#72]
```

The program is located from &B5F to &CFF, using all of the user defined character space (though this is of no consequence since there is no need to RUN the program to be compacted), and part of the user-key buffer space. There is still room to define some keys however, and to make use of this fact the version listed in this article uses 7 of these keys for a purpose:

```
10 REM PACK2 (c) David Tall 1982
20 REM version 1.20
30 REM (inspired by Graham Taylor's PACK)
40 REM Machine code version
50 REM to reside in pages &B00, &C00
60 REM RUN the program & then
70 REM *SAVE "PACK2" B00 D00 B73
80 REM The *SAVED program may be *RUN
90 REM to compact BASIC programs.
100 REM Reply Y to SPACES? to remove
110 REM redundant spaces. <Necessary
120 REM ones such as the one in
130 REM IFA=B C=D will be kept.>
140 REM Reply Y to REMS? to remove REMs.
```

```
f0 PAGED MODE 6            f4 *RUN
f1 LIST                    f5 RUN
f2 COMPACT                f10 OLD
f3 FREE SPACE
```

### SETTING UP PACK2

The procedure for setting up this version is simpler than the previous one and is identical for disc or cassette use.

1) Type in the Basic program and SAVE a copy for the sake of safety. A lot of the program is machine code so be very careful as you type it in. Anything after (and including) the '\ character in a line of machine code, up to the end of that line, may be discarded as this is a comment only. It is vitally important that you do type it in correctly because if you do not the program will not run, and no sensible error messages will be displayed.

2) RUN the program.

3) Perform a \*SAVE "PACK2" B00 D00 B73

After the above operations you should have two things on tape. One is the assembler listing (or source code), the second is the actual machine code which you will execute each time you want to perform a compaction. It is this second copy which will now be referred to as 'PACK2'.

### USING PACK2

There are two ways of running this version. First Load in the program to be compacted. Then you can perform a \*LOAD "PACK2" in order to load the compacter into memory, and then use key f2 to compact your program. Alternatively after loading the program to be compacted you could simply do a \*RUN "PACK2" which will automatically load (from tape or disc) the machine code, and then run it from the execution address &B73. Incidentally with a disc system (and therefore O.S 1.0) you can in fact just type \*PACK2 and the disc operating system will search for PACK2, load it and run it automatically, providing that it is in the designated library area and is not a reserved word (eg. we cannot use the title 'COMPACT'). In this way one can create a series of new commands that can even be used within a Basic program (though PACK2 should NOT be called in this way, for obvious reasons).

Note that the program automatically uses the current value of PAGE to find your program, in order to compact it.

We are most grateful to David Tall for the work which he has done on this program.

```
150 REM Reply Y to COMMENTS? to delete
160 REM comments in assembler coding.

## SINGLE KEY MEMORY DISPLAY (16k)

by Alan Cocker

Thanks to Alan Cocker for sending in this well written program. This is a very small program which will quickly and clearly display in hex and character (ASCII) format any desired area of memory. The program is so small that Alan has strung it together as a single line program which can be entered within a function key. This makes it extremely handy as it can be loaded and stored totally independently of any other program.

### INSTRUCTIONS FOR USE

- 1) Type the program in exactly as listed below, and run it.
- 2) To save a copy of the program, which is now stored within the function key buffer, use \*SAVE "DISPLAY" B00 C00
- 3) To reload the program at any time use \*LOAD "DISPLAY". This will reload the program into the function key buffer again, without disturbing any other program you may have in the computer.
- 4) To run the program hit the red function key 8. The screen will clear and you will be prompted for a "Start" address. This may be entered in decimal, hex or as any valid expression. (To enter a hex number, precede it with &). Then hit return and a ? will appear on the screen. This is the prompt for the number of bytes that you want displayed. Once again this may be decimal, hex or an expression.

The display will then commence. Each line is preceded with the address in hex, of the first byte on the line. This is followed by 8 bytes displayed in hex, and then in ASCII. If the ASCII display is an unprintable character, it is displayed as a full stop. This default unprintable character may be altered by inserting the value of the required character in place of the "46" in the program. The program does not use paged mode, so if more than a full screenfull of display is created, use CTRL and SHIFT keys, held down together to allow scrolling through the display. If you require a printout of the display, simply activate the printer in the normal way before hitting function key 8.

**\*\*NOTE\*\*** A tip for typing the program in. The character string in the last line is (R<32 OR R> etc ..ie the character after 32 is not zero.

### Program listing:

```
10*KEY8 MO:7:I."START, >"S$,N$:S=EV.S$:N=EV.N$:F.I=S TOS+N S.8:@%=4:P.~I;:B$=" "
:F.J=@T07:R=I?J:P.~R;:@%=3:R=R+(R<32 ORR>126)*(R-46):B$=B$+CHR$R:N.:P.B$:N:@%=10|M
```

### PROGRAM EXPLANATION

Mo:7:	Set Mode for display
Input "Start, >" S\$,N\$	Get Start Address and Number
S=Eval (S\$):	Evaluate Start (in case hex)
N=Eval (N\$):	Evaluate Start (in case hex)
For I=S To S+N Step 8:	Loop round memory requested
@%=4:	Set for correct printing
Print ~I;:	Print address of 1st byte hex
B\$="":	Initialise ASCII store
For J=@ To 7:	Loop round each byte on line
R=I?J:	Get contents of byte

```

Print ~R;:          Print contents in hex
@%=3:              Set for correct printing
R=R+(R<32 OR R>126)*(R-46):
B$=B$+Chr$(R):    Use "." (46) if out of range
Next J:            Add into ASCII store
Print B$:          Print ASCII at end of line
next I$:           Reset printing to normal
@%=10
IM

```

Example output:

The output shown below is a display of the start of the function key buffer. As the program in this article was the first function key program to run after a cold start, you can see it stored at the beginning of the buffer:

```

START, >&B00          B30 4E 3D 45 56 2E 4E 24 3A N=EV.N$:
?100                 B38 46 2E 49 3D 53 20 54 4F F.I=S TO
B00 AB AB AB AB AB AB AB AB ..... B40 53 2B 4E 20 53 2E 38 3A S+N S.8:

B28 53 3D 45 56 2E 53 24 3A S=EV.S$:

```

## POSTBAG

re:GAMES PROGRAMS

Dear BEEBUG,

I am writing to congratulate you on your program 'ASTRO-TRACKER', ...Myself and my friends have had BBC micros for about a year now and have been playing a lot of the Acornsoft/BEEBUG games, our high scores so far are as follows:

SNAPPER about 128,000

ARCADIANS 8670

DEFENDER (PLANETOID) around the 8 million mark, (yes, 8,000,000).

ASTRO-TRACKER about 13,000

John Benfield.

[Ed: can anyone beat 8 million at PLANETOID? We have already exceeded the ARCADIANS score with 15,000 and ASTRO-TRACKER with 22,000].

re:MAGIC EEL

Dear Sirs,

I recently bought a copy of GAMES 4 'MAGIC EEL'. It does not run on my machine. I have a Model B which appears to be fitted with the 1.0 O.S., and the switch-on message includes the message 'DFS'. After some days of worry and experimentation I can now load cassettes by using the \*TAPE command. Could this affect the 'MAGIC EEL' program? The program appears to load

perfectly and presents the page of instructions. However, when the SPACE bar is pressed the machine reverts to command mode. Any suggestions?

R.A. Walker.

[Ed: The loading of 'MAGIC EEL' using \*TAPE on a disc system does NOT affect it adversely. However, the program requires graphics MODE 1 to run, and the above effect occurs because you have not reset PAGE to &E00. Please see BEEBUG vol.1 no.7 p.27 (PAGE change hint) and BEEBUG vol.1 no.8 p.38 (Points Arising)].

re:USER PORT

Dear Sirs,

I was very interested in your articles on the user port in BEEBUG nos.3 and 4. In the article in no.4 you mentioned the IC 74LS17, in the accompanying diagram it was given as 74LS16. Whichever it is (and perhaps it does not matter?), I cannot find a supplier of it. Can you help me? Torben Hesselbo.

[Ed: Either device will do the job but you can use a non-LS type which may be more readily available in shops].

Program tested on  
0-1 and 1-1 O.S.

## FIVE-DICE (16k)

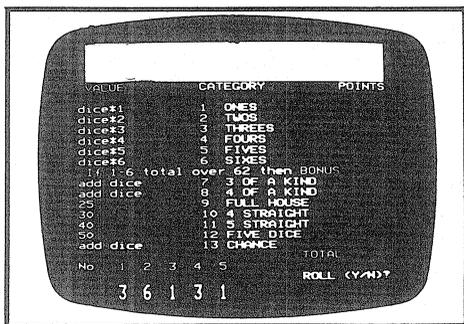

by Brian Kilby

This program simulates the dice game "YAHTZEE" (r), in which five dice are thrown and a score is given for their value, depending on the category in which the player puts it. The game requires a fair amount of skill and judgement, although luck does play its part. The program uses coloured teletext graphics in an exemplary way.

You are allowed a maximum of three re-throws on any number of dice, and then you must place the result in one of the categories listed.

Full instructions can be listed when the program is first run (the instructions appear in a novel way), and a high score is kept. If you are unfamiliar with the game, do not be daunted by the rules, these are soon picked up. We found this game good fun to play.

[NOTE: when playing, if you get 5 numbers of the same value eg 66666 this CANNOT be put down as a full house.]

```

PROCEDURES
init      Initialises variables, clears screen.
screen    Prints the title and categories.
roll      Throws dice and allows two more goes,
          calls FNchoice, calls test subroutine,
          and awards points.
Fntest1(number%) Checks if dice (1-5)=number% and
          returns value of quantity*number%, tests
          for categories 1-6.
Fntest11 Sorts dice into numerical order and
          checks if either 12345 or 23456 exist.
Fntest10 Checks if dice equal 1234, 2345 or 3456,
          other dice can be any value.
Fntest9 Checks for a 'Full House' (doesn't allow
          five of a kind).
Fntest7(number%) Tests for 3,4, or 5 of a kind.
FNadd     Returns the total value of the dice.
sort      'Bubble' sorts the dice into numerical
          order.
throw(dice$) Assigns new value to dice chosen.
clear     Clears the screen.
bonus     If categories 1-6 add up to more than
          62, then a bonus of 30 is added to the
          scoresheet.
choice    Main part. Asks if another roll is
          required, which category to score, and
          returns value of category.
dice      Prints dice in double height characters.
end       Prints total score and best score.
wait      Waits for the 'space' bar to be pressed.
read(N)   Reads N lots of data, and prints it at
          slow speed for the instructions.

**NOTE - In the game of FIVE-DICE some of the
instructions (held in DATA statements) are in fact
colour coded teletext characters. The lines
concerned are 1790, and 1830-1920. In the original
program they are mostly GREEN with the odd one in
MAGENTA (see listing). If you would like to keep
this feature or use different coloured teletext
characters, then do one of the following: If you
have 0.1 OS see the article in BEEBUG v1 no4 p7; if
you have a series 1 OS then see the hint in this
issue.

```

## POINTS ARISING

PACK article (BEEBUG v.1 no.8 p.12)

There is a problem with the Compacker Program published in the last issue. See the article 'Compacker revisited' in this issue, for an update on this program.

OSBYTE hint (BEEBUG v.1 no.8 p.41)

In the last issue we gave details of the useful OSBYTE 135 to find out what screen mode you were in. Contrary to what we said, this DOES work on O.S 0.1.

BAD PROGRAM article (BEEBUG v.1 no.8 p.4)

Under the heading 'THE PROGRAM' all references to line numbers in the SECOND paragraph must be incremented by 10, (ie. 'line 110' should read 'line 120').

BREAKOUT

For improved colour sequences on Breakout change line 20 to 20 VDU 19,1,1,0,0,0. When using the 16k version of the game do NOT delete line 1330 (contrary to instructions). Note this only affects error handling.

## HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS HINTS

COLOURED LISTINGS (TELETEXT)

In issue 4 of BEEBUG (p.7) there is an article on teletext characters for the (then) 0.1 OS. On a 1.0 OS coloured or flashing characters can be obtained in mode 7 merely by using the SHIFT key in conjunction with the red user keys (ie. by pressing SHIFT and a user key simultaneously). This can be used to good effect in the documenting of programs.

MOVING THE GRAPHICS ORIGIN

There is a built in command to shift the graphics origin on the Beeb. After executing VDU 29,X;Y; all PLOTS and DRAWS will be shifted by the amount X,Y. This can be extremely useful, and we are grateful to Paul Livingstone for this one. [We used this command in the very first issue of BEEBUG in the "3-D Noughts & Crosses" program in line 1770, but never included it as a 'hint & tip'. Ed.]

DISC-CASSETTE BREAK

If you have a disc filing system (DFS) ROM fitted, then it is well known that pressing CTRL/BREAK (ie. pressing CTRL and BREAK simultaneously) will cause a cold system restart to the DFS. Did you know that pressing T/BREAK or TAB/BREAK will cause a restart to the cassette filing system (CFS)? Thanks to K.Simpson for this hint.

It is true that pressing TAB/BREAK has the same effect as a CFS restart, but the value of PAGE remains set for the DFS, ie. at &1900.

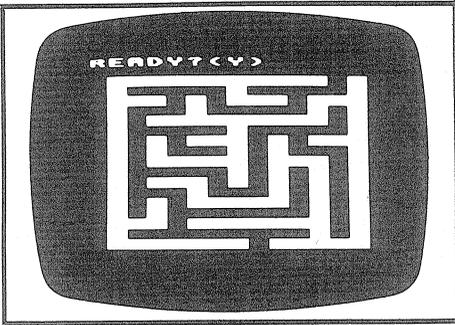

Program tested on  
0-1 and 1-1 O.S.

## BEEBMAZE (32k)

by R R Hull

It makes a change to have a program that doesn't involve death and destruction. This game retains some of the excitement of arcade type games, but gives you time for thought between each move, and can be quite addictive.

The program creates a random maze, and you have to find your way through to the exit. You are awarded a score depending on several factors. The interest comes because the screen displays the view that you would see if you were actually within the maze itself. The graphics are good, but you need both a good memory and sense of direction to get through the maze in record time.

When you get hopelessly lost, which you will to begin with, you can ask for a plan view of the maze (you lose points though) so that you can find out precisely where you are.

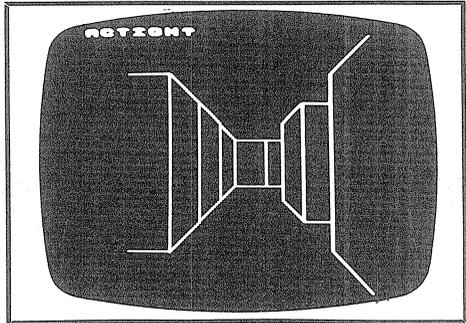

You simply control your movements with L R F A M which are turn left, right, move forwards, about turn, and request map.

There are two versions of the game, one timed and the other untimed. In the timed version you start with a certain amount of points, and lose them as follows:-

- 1 point per elapsed second
- 2 points per move
- 10 points for hitting a wall

50 points for leaving via the entrance  
100 points for requesting a map  
You GAIN 200 points for passing through the exit.

Finally if you want to change the range of sizes of the generated mazes study line:-

```
1090 line=20:width=RND(4)+4:height=RND(6)+7
```

You need to alter 'width' and 'height'. For example as it stands it will generate random widths from 5 to 8. Alter it to width=RND(2)+8 and it will generate widths from 9 to 10 only. The same applies to height. (Keep the number in brackets between 2 and 8). You can, of course, remove the random function altogether.

Please note that while this program works very well, and is good graphically, it does employ some rather unusual techniques - such as the 'pokes' and use of HMEM at line 1140 etc. We would not normally advise the use of these in such a program because they obscure understanding of the program operation, and prevent it from working across the Tube.

Please note, if you are using a disc system that you will sometimes run out of memory. You could either remove the instruction lines, or use the 'Move down' routine published elsewhere in this issue.

```

## WORDWISE Word Processor

BEEBUG Discount 13% SAVE £5

This is a highly sophisticated word processing package for the BBC Micro, and compares very favourably with those currently available on other microcomputers. It makes full use of the BBC micro's advanced facilities, and text is typed and edited in the 40 column Teletext mode, saving memory, thus allowing it to be used with more or less any TV. See the software review in this issue for further details.

Wordwise is supplied in EPROM with simple fitting instructions, a full manual, and a sample data cassette. Wordwise must be used in conjunction with a series 1 operating system.

The normal price of Wordwise is £39+VAT=£44.85 (plus p&p)

To BEEBUG members it is £34+VAT=£39.10 plus 90p post & packing=£40.

Make cheques payable to BEEBUG and send to:

## BEEBUG NEW ROM OFFER

---

### ACORN PRESS RELEASE TO BEEBUG MEMBERS

A special arrangement has been agreed between Acorn and BEEBUG whereby BEEBUG members may obtain the Series One Machine Operating System in ROM at the price of £5.85 including VAT and post and packing.

The ROM will be supplied with fitting instructions to enable members to install it in their machine.

If the computer does not subsequently operate correctly, members may take their machines to an Acorn dealer for the upgrade to be tested, which will be done at a charge of £6.00 plus VAT. This charge will be waived if the ROM is found to have been defective. If the computer has been damaged during the installation process, the dealer will make a repair charge.

### NOTES ON ORDERING

1. To get a new ROM, BEEBUG members should send a cheque for £5.85 to ROM Offer, BEEBUG, PO Box 109, High Wycombe, Bucks, HP11 2TD. It is ESSENTIAL to include a cheque with order, and to give your membership number.
2. ROM orders must not be combined with any other order - eg for software etc; and because of constraints on supply, multiple orders cannot be accepted until further notice.
3. Because of uncertainties in supply, please allow 4-6 weeks for delivery. We undertake not to cash cheques until the week prior to despatch; and we will provide a monthly account of the supply situation in BEEBUG. Please keep a note of the date on which you posted your order so that you can relate this to future announcements.
4. Please note that we cannot accept EPROM-based 0.1 operating systems in lieu of payment. The exchange of EPROMs for the new operating system can only be performed by Acorn dealers or by Acorn's service centre at Feltham.

ADDRESS: ROM Offer, BEEBUG, PO Box 109, High Wycombe, Bucks, HP11 2TD.

## NOTICE BOARD

---

### SOFTWARE LIBRARY

Please note new address for members software library:  
BEEBUG Software, PO BOX 109, High Wycombe, Bucks, HP11 2TD.

### PAYMENT FOR CONTRIBUTIONS

New rates of pay for BEEBUG contributions covering Hints, Programs and Articles: see outer cover of this issue for details.

### MEMBERS' PERSONAL ADS

We are starting a regular personal ad page in the magazine supplement. Rates are 15p per word for members' personal ads. Members' business ads cost 25p per word - and if you are selling any item in quantities rather than one-off, then that counts as business. In either case send cheque with order. Post to PERSONAL ADS, BEEBUG, PO BOX 50, St Albans, Herts, AL1 2AR. It is ESSENTIAL to include your membership number. Please note that we cannot arrange for box numbers.

IF YOU WRITE TO US

BACK ISSUES (Members only)

All back issues are kept in print (from April 1982). Send 90p per issue PLUS an A5 SAE to the subscriptions address. This offer is for members only, so it is ESSENTIAL to quote your membership number with your order.

Software Address  
BEEBUG  
PO BOX 109  
Baker Street  
High Wycombe  
Bucks  
HP11 2TD

IDEAS, HINTS & TIPS, PROGRAMS, AND LONGER ARTICLES

Substantial articles are particularly welcome and we will pay around £25 per page for these, but in this case please give us warning of anything that you intend to write. In the case of material longer than a page, we would prefer this to be submitted on cassette or disc in machine readable form using "Wordwise", "Minitext Editor" or other means. If you use cassette, please include a backup copy at 300 baud.

We will also pay £10 for the best Hint or Tip that we publish, and £5 to the next best. Please send all editorial material to the editorial address opposite. If you require a reply it is essential to quote your membership number and enclose an SAE.

Editorial Address  
BEEBUG  
PO Box 50
